Perfume Oil Website: Back End Instruction

Task: Build a back end for my perfume oil website. My front end is plain HTML/CSS/JS. Keep my design. Build in small steps and wait for my "done" before the next step.

How the business works: The customer fills an order form on the website. The order is saved automatically, then WhatsApp opens with the order message ready. The seller confirms the order with one tap after the customer pays. She never types sales by hand.

Tech: Node.js + Express + SQLite. Simple code, with comments in plain English.

Seller dashboard language: French and Lingala. Add a language switch button (FR / LN). Put all dashboard text in one translation file so I can fix the Lingala words easily.

Mobile friendly: The seller will mostly use her phone. Every seller page must work well on a small screen: big buttons, tables that scroll sideways or turn into cards, no tiny text.

Step 1: Products and stock

- Add, edit, delete a perfume oil (name, size, price, quantity)
- Low-stock warning at 5 or less

Step 2: Seller login (before any seller page)

- Every seller page (products, orders, dashboard) is protected. Anyone not logged in is sent to the login page
- **No public sign-up page.** Nobody can create an account from the website
- **First seller account:** read a username and temporary password from the .env file and create the account **one time** when the server first starts (only if no seller exists yet)
- Passwords hashed with bcrypt, never plain text
- Add a **"Change password"** page so the seller can choose her own password after her first login
- Sessions and a logout button
- Add .env to .gitignore so it never goes to GitHub
- Go back to Step 1 and protect the product pages with this login

Step 3: Order form on the website

- The product list **loads from the database** (no fixed list in the HTML). Hide out-of-stock products
- Customer picks the oil and quantity, and enters name and phone number
- The order is saved in the database with status **"pending"**
- Then WhatsApp opens with a ready message (product, quantity, total, order number)
- Block the order if there is not enough stock

Step 4: Confirm orders (seller)

- List of orders: pending and confirmed
- One **"Confirmed"** button per order
- **Check the stock again when she taps Confirmed.** If there is not enough stock, show a warning and do not confirm (this stops two customers from buying the last bottle)
- Confirmed = counts as a sale and lowers the stock
- A **"Cancel"** button for orders that are never paid (stock stays the same)

Step 5: Dashboard

- **Inventory table (tableau d'inventaire):** for each product show starting stock, quantity sold, stock left, money earned
- **Sales per day:** table and simple chart (confirmed orders only)
- Money earned today, this week, this month
- Best-selling and slowest-selling oils

Step 6: Visitors and buyers

- Count one visit per person per day
- Dashboard shows: visitors per day, orders placed, orders confirmed
- **Conversion rate** = confirmed orders ÷ visitors, as a percentage

Rules

- Secrets go in a .env file, never in the code
- Validate all inputs (no negative quantities, no empty names, phone number format)
- After each step, tell me how to test it
- Explain the code in very simple English, because I am a beginner
